It lets you work.Orthogonal Frequency Division Multiplexing (OFDM) modulation is a popular technique for transmitting data in wireless communication systems. In an OFDM system, a signal modulated onto an OFDM carrier is translated into a number of narrowerband (carrier) signals using an IFFT operation, such as the OFDM Modulator described in IEEE 802.11, at the transmitter. At the receiver, the individual carriers are then demodulated and combined into a stream of data. Signals may be passed through a channel with the intention of using an IFFT to reconstruct the original signal. For some OFDM implementations, such as IEEE 802.11, the carriers are separated into a number of channels, such as 23 subcarriers as described in IEEE 802.11. A portion of the subcarrier is used to transmit data, while the other subcarriers do not carry data. Subcarriers are also used to transmit a pilot tone to aid in the IFFT estimation and channel tracking. Another important use of the subcarriers is for the ACK/NACKs. Each subcarrier carries either an ACK or a NACK. The information may be sent at a rate equivalent to the bit rate. The transmission rate is substantially higher than the bit rate of the data, since each symbol typically contains more than one bit. As a result, the duration of the transmission symbol is much longer than a single bit. For clarity, a symbol is abbreviated “
